Nursing care for prevention of skin injury in pre-term newborn: Integrative review

Descritores: Recém-nascido; Pré-termo; Pele; Cuidados de enfermagem.

ABSTRACT | Objective: to describe nursing care to prevent skin lesions in preterm newborns in the Neonatal Intensive Care Unit. Method: integrative review carried out in the CINAHL, MEDLINE, LILACS and BDENF databases, in July 2021, with 16 articles being selected, published between 2015 to 2020. Results: In the studies, it was observed that there are numerous care and products used to maintain and prevention skin integrity, such as: thermoregulation, changing diapers, use of emollients, daily skin assessment, bathing, use of antiseptics. Conclusion: It is observed that there is a lack of studies with high-level evidence, which help in the formation of care in practice with safety for newborns, and more studies related to the subject are essential.
Keywords: Newborn; Preterm; Skin; Nursing care.

RESUMEN | Objetivo: describir los cuidados de enfermería para la prevención de lesiones cutáneas en recién nacidos prematuros en la Unidad de Cuidados Intensivos Neonatales. Método: revisión integradora realizada en las bases de datos CINAHL, MEDLINE, LILACS y BDENF, en julio de 2021, siendo seleccionados 16 artículos, publicados entre 2015 y 2020. Resultados: En los estudios se observó que existen numerosos cuidados y productos utilizados en mantenimiento y prevención de la integridad de la piel, tales como: termorregulación, cambio de pañales, uso de emolientes, evaluación diaria de la piel, baño, uso de antissépticos. Conclusión: Se observa que faltan estudios con alto nivel de evidencia, que ayuden en la formación del cuidado en la práctica con seguridad para los recién nacidos, siendo imprescindible más estudios relacionados con el tema.
Palabras claves: Recién nacido; Prematuro; Piel; Cuidado de enfermera.

INTRODUCTION

According to the World Health Organization, preterm newborns (PTNBs) are those with a gestational age of less than 37 weeks, being divided into subcategories according to gestational age, being extremely premature (less than 28 weeks), very premature (28 to 32 weeks), and moderate to late preterm (32 to <37). Currently, the prematurity rate in Brazil is 11.5%, one of the highest in the world, and one of the main factors of infant mortality.

Newborn skin comprises approximately 13% of the body surface and one of its main functions is to act as a protective barrier. In addition to this extremely important function, the skin assists in thermoregulation, minimizes transdermal water loss, prevents the absorption of chemical agents, protects against infectious agents and immunosurveillance.

Technological advances have allowed the survival and reduction of infant mortality of PTNBs in the Neonatal Intensive Care Unit (NICU), despite being an environment in which newborns are exposed by manipulations and various procedures such as venipuncture, blood collection, use of dressings, it is extremely important to take care of the skin of the PTNB, which has an ineffective skin barrier function, because the stratum corneum is not fully formed, considerably increasing the risk of injury. Consequently, it can significantly contribute to the increase in sepsis.

The skin lesion in the PTNB is one of the factors that contributes to a longer hospital stay, being important for public health, impacting the life of the PTNB, systematic actions by the nursing team in the care of the PTNB are necessary, which must be developed in an integral way and a routine evaluation of the skin, identifying...
and eliminating the risk factors that cause injuries.  

It is important to highlight that 80% of newborns develop a skin lesion within the first month of life, especially PTNBs, and may acquire an incident related to sepsis, with the skin being the main gateway.  

In this scenario, maintaining the integrity of the PTNB’s skin is a constant challenge in the nurse’s work activity and one of the primary care in nursing. The nursing team has a fundamental role in the care and maintenance of the PTNB’s skin integrity, which indicates the need for scientific knowledge with the use of evidence-based clinic, in order to minimize complications caused by hospitalization and the characteristics of your skin for safe care.  

Faced with the problem, the guiding question of the study arises: What are the nursing care to prevent skin lesions in preterm newborns? Thus, this study aimed to describe the care to prevent skin lesions in PTNBs in the NICU.  

METHOD  

This is an integrative review, following the following steps: elaboration of the guiding question; definition of inclusion/exclusion criteria for articles; literature search of selected databases; definition of analytical axes; evaluation of included studies; interpretation of results and presentation of the review.  

The formulation of the guiding question was inspired by the PICO strategy (population/intervention/comparison/result), where P: preterm newborn, I: nursing care to prevent skin lesions, CO: maintenance of skin integrity. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) checklist was used.  

The selected databases were: BDENF (Nursing Database), CINAHL (Cumulative Index to Nursing and Allied Health Literature), LILACS (Latin American and Caribbean Literature in Health Sciences), MEDLINE (Online Search and Analysis System of Medical Literature). For the LILACS and BDENF databases, the Health Sciences Descriptors (DeSC) were used: pele, pré-termo, recém-nascido e cuidados de enfermagem, being used for the search the Boolean operators AND and OR (pele AND pré-termo OR recém-nascido AND cuidados de enfermagem). For the CINAHL and MEDLINE databases, the MeSH (Medical Subject Headings) descriptors were used: skin, newborn, pre-term, nursing care, with the help of the Boolean operators AND and OR (skin AND preterm OR newborn AND nursing care).  

The selection of articles was carried out in July 2021, published between 2015 and 2020. Inclusion criteria were: full texts, published in Portuguese, Spanish and English. For exclusion, the criteria were: those that did not have full text, abstract, repeated in the databases or that were outside the theme, or that were paid.  

For data analysis, the level of evidence of the study was used, where the data were structured and synthesized, reinforcing the development of the theme, using the model based on the categorization of the Agency for Healthcare Research and Quality (AHRQ)  

The following flowchart shows the drill down. (figure 1).  

RESULTS  

The final sample consisted of 16 articles, as shown in the table below. It was observed that 4 articles were published in 2015, 1 in 2016, 2 in 2017, 1 in 2018, 5 in 2019 and 3 in 2020, and it was found that the topic is relevant. It was possible to observe that most studies had level V1 evidence.  

According to the reading of the studies, several precautions for injury prevention were identified. Among them, the following stand out: use of emollients, use of antiseptics, change of position, transdermal loss, actions to promote thermoregulation, skin assessment, use of adhesives, hygiene and bathing. The following were extracted from the articles: Article enumeration (EA) according to chronology and Level of Evidence, Title, Author, Year, Country, Method, nursing care, presented in table 1.  

DISCUSSION  

Nursing care related to the skin of PTNB requires scientific knowledge from professionals to play an important role in the quality of care, acting in the prevention and maintenance of skin integrity. The selected studies made it possible to com-
pills recommendations regarding the care of the skin of the PTNB.

After the birth of the newborn, maintaining thermoregulation is one of the main precautions in skin care, as hypothermia can lead to hypoglycemia, metabolic acidosis and hypoxia. Therefore, health professionals need to adopt measures such as placing a cotton cap on the head to reduce heat loss, use of polyurethane film. 11

According to the WHO, the normal temperature of newborns is between 36.50C and 37.0C, and thermoregulation is an important factor after birth, as the risk of hypothermia is greater, due to the adequacy of the extraterrestrial environment, increasing the risk of mortality. 12 That said, the importance of the nurse’s role for a better transition of the NB to the extraterrestrial environment is observed.

Article 7 describes humidified incubators and heated cribs as resources used to avoid hypothermia and assist in maintaining thermoregulation, as there is a decrease in evaporative loss, a decrease in transepidermal water loss, electrolytes, thus avoiding thermal instability. Since the PTNB’s skin has the absence or reduction of vernix, making the skin more vulnerable. 11

The maintenance of humidification in the incubator should be maintained at 85% during the first week of life, and after that it should remain at 70% until the third week and gradually reduce to 60% and after maintaining 60% until the neonate reaches 1500g, being indicated for PTNB below 1000g and gestational age below 30 weeks. 13

One of the strategies adopted for the prevention of skin lesions is the use of a polyethylene bag, reported in a randomized study, which shows the effectiveness in thermoregulation of preterm neonates, below 34 weeks, reducing heat loss by convection and evaporation. It was observed that covering the PTNB with a polyethylene bag for one hour is more effective than covering the newborn with a cloth, reducing the incidence of hypothermia and keeping the NB warmer. 14

Another important care related to skin maintenance is bathing, which is recommended not daily, as they can increase the pH of the skin, damage the maturation of the acid mantle, increase oxygen consumption, and, consequently, cause respiratory discomfort. It is recommended to alternate bathing with neutral soaps and bathing only with water since the pH of the newborn’s skin at birth is neutral, however, in a few days, it becomes acidic. In PTNBs younger than 26 weeks, it is recommended to use only sterile water for bathing and in PTNBs younger than 32 weeks, it is recommended to use sterile warm water. Daily cleaning is not recommended in premature infants, and this procedure must take into account the level of consciousness, behavioral response and clinical status of the baby. 15, 16, 17

According to article 14, reducing the bath interval from two to four days reduces the risk of hypothermia, promoting an environment for development and growth, consequently decreasing the risks of physiological instability, not increasing the incidence of axillary colonization or skin problems, being a safe, evidence-based nursing intervention. 13

The use of antisepsics is essential for the performance of invasive procedures, as newborns hospitalized in NICUs are susceptible to the appearance of infections related to health care, so it is essential to choose the best product without causing harm to the NB. 18

The use of antiseptic can cause burns, especially if alcohol or alcohol-based chlorhexidine is used. Thus, according to the article, the use of 0.2% chlorhexidine as a skin disinfectant for extremely preterm infants resulted in a reduction in lesions, without increasing bloodstream infection compared to 0.5% chlorhexidine, with alcohol, being indicated for extreme preterm infants less than 26 weeks of gestation. 19

A study in a maternity hospital analyzed the care of the skin of the preterm newborn by the nursing team, the most mentioned care were bathing and body hygiene, changing the position and hydration of the skin, one of the main precautions described is the use of emollients.

such as sunflower oil for hydration and protection from transepidermal loss.\(^{13}\) A study in a maternity hospital analyzed the care of the skin of the preterm newborn by the nursing team, the most mentioned care were bathing and body hygiene, changing the position and hydration of the skin, one of the main precautions described is the use of emollients such as sunflower oil for hydration and protection from transepidermal loss.\(^{12}\)

Another study that aimed to evaluate the effects of topical application of coconut oil on the skin of premature babies, found that it improves weight gain, reduces the risk of infection, improves skin condition, and can prevent hypothermia and apnea. These findings demonstrate that coconut oil can be a beneficial emollient for premature newborns, due to its properties.\(^{17,18}\)

The A 11, tested the impact of sunflower seed oil and mustard seed oil on skin barrier function in newborns, where the resource is scarce. In general, it was observed that pH, transepidermal water loss and skin conditions in the sunflower oil group compared to the mustard seed oil group did not differ in terms of gestational age.\(^{20}\)

According to A16, the care provided by nursing to maintain skin integrity and prevent injury is directed to the skin of premature infants, from admission to discharge. Among these precautions, there are the sensor rotation, the use of tencosoplast, the administration of sunflower oil, and the use of hydrocolloid.\(^{23}\)

The A5 and 6 describe strategies and the importance of preventing skin lesions in the perianal region, being one of the lesions that most affect the NB in the NICU, such as: changing diapers every 3 hours or when dirty, cleaning with water and cotton without the use of soap, frequent skin assessment, use of diapers with high absorption, and the use of products that establish a barrier function.\(^{14,15}\)

As the PTNB in the NICU is predisposed to the appearance of pressure injuries due to skin immaturity, impaired mobility, inappropriate nutrition and medical devices, which are essential for the preservation of life.\(^{16}\) In order to avoid injuries, it is advisable to use an egg crate mattress, change the position every 3 or more frequently, cradle the baby in the fetal position, simulating the environment of the uterus, use of silicone and hydrocolloid-based protectors between the device and the skin.\(^{4,8,14,16}\)

The application of technology in the health area has helped in the care strategy, especially in the neonatal area. A survey carried out on the evaluation of the quality of the Neonatal Skin Safe software, used in the prevention of skin injury, is a way to contribute to patient safety and better quality, guaranteeing access to evidence-based knowledge, enabling the nurse to make a general assessment of the NB, identify diagnoses and suggest nursing interventions.\(^{12}\)

**CONCLUSION**

The need for nurses to provide effective measures and individualized care to PTNBs within the NICU is emphasized, for a better quality of care provided.

In the construction of the study, it was observed that there are numerous care and products used in the maintenance and prevention of skin integrity, such as: sensor change, incubator humidification, diaper change, use of emollients, daily skin assessment, cleaning and bathing, use of anti-
septics, more than the lack of protocols, it makes it difficult to incorporate these practices into care.

It is observed that there is a lack of studies with high-level evidence. In this study, few articles with a high level of evidence were identified and most articles were based on expert opinion. It is essential that more studies related to the topic are carried out, aiming to improve the level of evidence and the development of care protocols for the care in question, contributing to better care.
